# 1 Protocol overview

Citadel is a self-sovereign identity (SSI) protocol built on top of Dusk that allows users of a given service to manage their digital identities in a fully transparent manner. More specifically, every user can know which information about them is shared with other parties, and accept or deny any request for personal information.

## 1.1 Properties

With Citadel, users of a service can request licenses that represent their *right* to use such a service. Citadel satisfies the following properties:

- *Proof of ownership*: users can prove that they own a valid license that allows them to use a certain service.
- *Proof of validity*: users with a valid license can prove that their license has not been revoked and is valid.
- *Unlinkability*: different services used by a same user cannot be linked from one another.
- *Decentralized session opening*: when users start using a service, the network learns that this happened and the license used to access to the service cannot be used again.
- *Attribute blinding*: users have the power to decide exactly what information they want to share and with whom.

## 1.2 The parties involved

Citadel involves three (potentially different) parties:

- The *user* is the person who interacts with the wallet and requests licenses in order to claim their right to make use of services.
- The *service provider* (SP) is the entity that offers a service to users. Upon verification that a service request from a user is correct, it provides such service.
- The *license provider* (LP) is the entity that receives requests for licenses from users, and upon acceptance, issues them. The LP can be the same SP entity or a different one.

## 1.3 Protocol flow [Missing explanation]

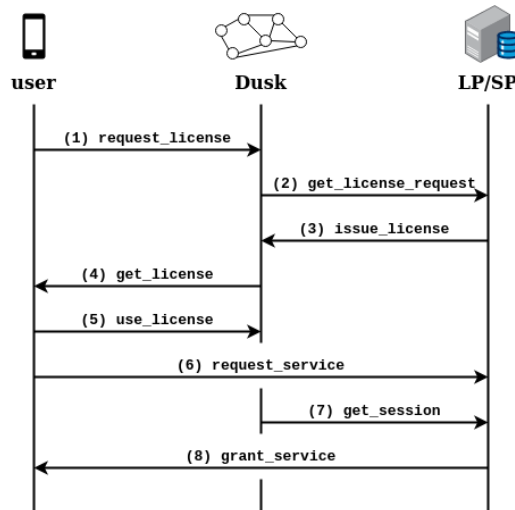

Figure 1: Overview of the protocol messages exchanged between the user, Dusk's network, and the LP/SP.

## 2 Building blocks

In this section, we present the static keys associated each party involved in the protocol, and also the structure of the elements involved.

Marta: I suggest to include a section with the details of the cryptographic elements included in this section (the jubjub group, the generators, etc.).

### 2.1 Cryptographic primitives

Marta: Hashing - it is going to be Poseidon everywhere.

### 2.2 Keys

Let  $G, G' \leftarrow \mathbb{J}$  be two generators for the subgroup  $\mathbb{J}$  of order  $t$  of the Jubjub elliptic curve. In Citadel, each party involved in the protocol holds a pair of static keys with the following structure:

- *Secret key*:  $\mathbf{sk} = (a, b)$ , where  $a, b \leftarrow \mathbb{F}_t$ .
- *Public key*:  $\mathbf{pk} = (A, B)$ , where  $A = aG$  and  $B = bG$ .

We use the subindices `user`, `SP`, `LP` to indicate the owner of the keys, e.g.  $\mathbf{pk}_{\text{user}}$ .

### 2.3 Elements involved

Here we describe the elements involved in Citadel. How they are used in the protocol is described in Section 3.

- *Request*: the structure of a request includes the encryption of a stealth address belonging to the user and where the license has to be sent to, and a symmetric key shared between the user and the LP.

Element	Type	Description
$(\mathbf{rpk}, R_{\text{req}})$	StealthAddress	Stealth address for the LP.
<code>enc</code>	PoseidonCipher[6]	Encryption of a user's stealth address where the license has to be sent to and a symmetric key.
<code>nonce</code>	BlsScalar	Randomness needed to compute <code>enc</code> .

- *License*: asset that represents the right of a user to use a given service. A license has the following structure:

Element	Type	Description
$(\mathbf{lpk}, R_{\text{lic}})$	StealthAddress	License stealth address of the user.
<code>enc</code>	PoseidonCipher[4]	Encryption of user attributes and signature of these attributes.
<code>nonce</code>	BlsScalar	Randomness needed to compute <code>enc</code> .
<code>pos</code>	BlsScalar	Position of the license in the Merkle tree of licenses.

- *SessionCookie*: a session cookie is a secret value only known to the user and the SP. It contains a set of openings to a given set of commitments. The structure is as follows:

Marta: The session cookie is not a secret value, it is an struct. Does it refer to `session_id`?

Marta: Clarify what the element `attr` is - is it a hash, an array?

Element	Type	Description
$pk_{SP}$	JubJubAffine	Public key of the SP.
$r_{session}$	BlsScalar	Randomness for computing the session hash.
session_id	BlsScalar	ID of a session opened using a license.
$pk_{LP}$	JubJubAffine	Public key of the LP.
attr	JubJubScalar	Attributes of the user.
$c$	JubJubScalar	Challenge value.
$s_0$	JubJubScalar	Randomness used to compute $com_0^{hash}$ .
$s_1$	BlsScalar	Randomness used to compute $com_1$ .
$s_2$	BlsScalar	Randomness used to compute $com_2$ .

- *Session*: a session is a public struct known by all the validators. The structure is as follows:

Marta: What does *validators* mean?

Marta: TODO - when we say *together with some randomness*, I would include the name of the random variable.

Marta: In  $com_0^{hash}$ , does the commitment also include some randomness?

Element	Type	Description
session_hash	BlsScalar	Hash of the SP's public key together with some randomness.
session_id	BlsScalar	ID of a session opened using a given license.
$com_0^{hash}$	BlsScalar	Hash of the public key of the LP.
$com_1$	JubJubExtended	Pedersen commitment of the attributes.
$com_2$	JubJubExtended	Pedersen commitment of the $c$ value.

- *LicenseProverParameters*: a prover needs some auxiliary parameters to compute the proof that proves the ownership of a license. Some of the items of this table are related to the session and session cookie elements. The structure is as follows:

Marta: TODO - when we say *together with some randomness*, I would include the name of the random variable.

Element	Type	Description
lpk	JubJubAffine	License public key of the user.
$lpk'$	JubJubAffine	A variation of the license public key of the user computed with a different generator.
sig <sub>lic</sub>	Signature	Signature of the license attributes.
$com_0^{hash}$	BlsScalar	Hash of the LP's public key.
$com_1$	JubJubExtended	Pedersen commitment of the attributes.
$com_2$	JubJubExtended	Pedersen commitment of the $c$ value.
session_hash	BlsScalar	Hash of the public key of the SP together with some randomness.
sig_session_hash	dusk_schnorr::Proof	Signature of the session hash signed by the user.
merkle_proof	PoseidonBranch	Membership proof of the license in the Merkle tree of licenses.

### 3 Protocol

Marta: Change BLAKE2 to Poseidon and leave a footnote.

In this section, we describe the workflow of Citadel in detail.

1. (**user**) request.license()

- 1.1. Compute a license stealth address  $(\text{lpk}, R_{\text{lic}})$  belonging to the user, using the user's own public key, as follows.
  - i. Sample  $r$  uniformly at random from  $\mathbb{F}_t$ .
  - ii. Compute a symmetric Diffie–Hellman key  $k = rA_{\text{user}}$ .
  - iii. Compute a one-time public key  $\text{lpk} = H^{\text{BLAKE2b}}(k)G + B_{\text{user}}$ .
  - iv. Compute  $R_{\text{lic}} = rG$ .
- 1.2. Compute the license secret key  $\text{lsk} = H^{\text{BLAKE2b}}(k) + b_{\text{user}}$  and an additional key  $k_{\text{lic}} = H^{\text{Poseidon}}(\text{lsk})G$ .
- 1.3. Compute the request stealth address  $(\text{rpk}, R_{\text{req}})$  using the LP's public key, as follows.

Marta: Consider using different letter instead of  $r$ ...

- i. Sample  $r$  uniformly at random from  $\mathbb{F}_t$ .
  - ii. Compute a symmetric Diffie–Hellman key  $k_{\text{req}} = rA_{\text{LP}}$ .
  - iii. Compute a one-time public key  $\text{rpk} = H^{\text{BLAKE2b}}(k_{\text{req}})G + B_{\text{LP}}$ .
  - iv. Compute  $R_{\text{req}} = rG$ .
- 1.4. Encrypt data using the key  $k_{\text{req}}$ :  $\text{enc} = \text{Enc}_{k_{\text{req}}}((\text{lpk}, R_{\text{lic}}) || k_{\text{lic}}; \text{nonce})$ .

Marta: Include how the nonce is computed, if it is a random value as well.

- 1.5. Send the following request to the network:  $\text{req} = ((\text{rpk}, R_{\text{req}}), \text{enc}, \text{nonce})$ .
2. **(LP)** `get_license_request()`  
 The LP checks continuously the network to detect any incoming license requests addressed to them:
    - 2.1. Compute  $\tilde{k}_{\text{req}} = a_{\text{LP}}R_{\text{req}}$ .
    - 2.2. Check if  $\text{rpk} \stackrel{?}{=} H^{\text{BLAKE2b}}(\tilde{k}_{\text{req}})G + B_{\text{LP}}$ .
  3. **(LP)** `issue_license()`
    - 3.1. Upon receiving a request from a user, define a set of attributes  $\text{attr}$  representing the license, and compute a digital signature as follows:
 
$$\text{sig}_{\text{lic}} = \text{sign\_single\_key}_{s_{\text{KSP}}}(\text{lpk}, \text{attr}).$$
    - 3.2. Encrypt the signature and the attributes using the license key:
 
$$\text{enc} = \text{Enc}_{k_{\text{lic}}}(\text{sig}_{\text{lic}} || \text{attr}; \text{nonce}).$$
    - 3.3. Send the following license to the network:
 
$$\text{lic} = ((\text{lpk}, R_{\text{lic}}), \text{enc}, \text{nonce}, \text{pos}).$$

4. **(user)** `get_license()`

In order to receive the license, the user must scan all incoming transactions the following way:

- 4.1. Compute  $\tilde{k}_{\text{lic}} = H^{\text{BLAKE2b}}(\text{lsk})G$ .
- 4.2. Check if  $\text{lpk} \stackrel{?}{=} H^{\text{BLAKE2b}}(\tilde{k}_{\text{lic}})G + B_{\text{user}}$ ,

#### 5. (user) use\_license()

When using the license, open a session with a specific SP by executing a call to the license contract. The following steps are performed:

Marta: We should mention something about the license contract before this step. Maybe in Section 2 where elements are presented? Add a small section about Dusk's blockchain?

- The user issues a transaction that calls the license contract, which includes a ZKP that is computed out of the gadget depicted in Figure ???. Notice that here, the user signs `session_hash` using `lsk`. Likewise, the user here will need to compute  $lpk' = lskG'$ .
- The network validators will execute the smart contract, which verifies the proof. Upon success, the following session will be added to a shared list of sessions:

$$\text{session} = \{\text{session\_hash}, \text{session\_id}, \text{com}_0^{\text{hash}}, \text{com}_1, \text{com}_2\},$$

where  $\text{session\_hash} = H^{\text{Poseidon}}(\text{pk}_{\text{SP}} || r_{\text{session}})$ , and  $r_{\text{session}}$  is sampled uniformly at random from  $\mathbb{F}_t$ .

#### 6. (user) request\_service()

Request the service to the SP, establishing communication using a secure channel, and providing the session cookie that follows.

$$\text{sc} = \{\text{pk}_{\text{SP}}, r_{\text{session}}, \text{session\_id}, \text{pk}_{\text{LP}}, \text{attr}, c, s_0, s_1, s_2\}$$

#### 7. (SSP) get\_session()

Receive a session from the list of sessions, where  $\text{session.session\_id} = \text{sc.session\_id}$ .

#### 8. (SSP) grant\_service()

Grant or deny the service upon verification of the following steps:

- Check whether the values  $(\text{attr}, \text{pk}_{\text{LP}}, c)$  included in the `sc` are correct.
- Check whether the opening  $(\text{pk}_{\text{SP}}, r_{\text{session}})$  included in the `sc` matches the `session_hash` found in the `session`.
- Check whether the openings  $((\text{pk}_{\text{LP}}, s_0), (\text{attr}, s_1), (c, s_2))$  included in the `sc` match the commitments  $(\text{com}_0^{\text{hash}}, \text{com}_1, \text{com}_2)$  found in the `session`.

Furthermore, the SP might want to prevent the user from using the license more than once (e.g. this is a single-use license, like entering a concert). This is done through the computation of `session_id`. The deployment of this part of the circuit has two different possibilities:

- If we set  $c = 0$  (or directly remove this input from the circuit), the license can be used only once.
- If the SP requests the user to set a custom value for  $c$  (e.g. the date of an event), the license can be reused only under certain conditions.
